

Muon g-2 Experiment

By studying the properties of muons, scientists at Fermilab hope to learn whether there are elementary particles beyond the ones we know.

The experiment

Muon g-2 (pronounced gee-minus-two) is an international collaboration between U.S. universities, Fermilab in Illinois, Brookhaven National Laboratory in New York, and nine international labs and universities. It is designed to probe the magnetic property of the muon, a heavy sibling of the electron that lives for about two microseconds, in greater detail than ever before.

The Muon g-2 experiment will study the rotation (wobble) of muons when placed in a magnetic field. Based on what we know about muons and other particles already, scientists should be able to predict the value of the muon's magnetic "wobble." If the experiment comes up with something different, it may mean that our current understanding of physics is incomplete, and could open the door to exciting new realms of science.

A similar experiment at Brookhaven collected data between 1998 and 2001. The margin of error on that experiment provided evidence for—but not definitive proof of—a departure from the expected value of the muons' wobble. That's where the Fermilab Muon g-2 experiment will come in, conducting a next-generation experiment with much greater precision.

Scientists stand inside the 50-foot-wide muon storage ring at Brookhaven National Laboratory in New York.

What are muons?

Muons are subatomic particles similar to electrons, but 207 times heavier.
 They carry the same electrical charge (negative) as an electron.
 They exist for only about 2.2 millionths of a second.
 They are very easy to make and store at Fermilab.
 When placed in a magnetic field, they spin like a gyroscope, and it is this property that the Muon g-2 experiment will measure.

The machine

The centerpiece of the Muon g-2 experiment is a particle storage ring made of steel, aluminum and superconducting wire. It measures 50 feet in diameter, and currently resides at Brookhaven in New York, where it was the heart of the 1990s experiment.

Fermilab has the ability to generate more muons than any other accelerator complex in the United States, and only needs the Brookhaven machine to store and study those muons. Since it is 10 times cheaper to move the existing magnetic ring than it is to build a new one, researchers plan to transport the ring by specially prepared barge and truck from the east coast to Fermilab in summer 2013. (See the back of this sheet for more.)

Researchers plan to install the massive ring in the laboratory's new muon campus, which begins construction in 2013. The Muon g-2 experiment will begin taking data in 2016.

Muon g-2 Experiment: From New York to Illinois

The big move

Fermilab will be able to produce the high-intensity muon beam necessary for the Muon g-2 experiment. Since building a new storage ring would be too expensive, the 50-foot-wide magnetic ring at Brookhaven will be moved from New York to Illinois. The move is planned for summer 2013, and project managers are working with local authorities and transportation specialists to make it happen.

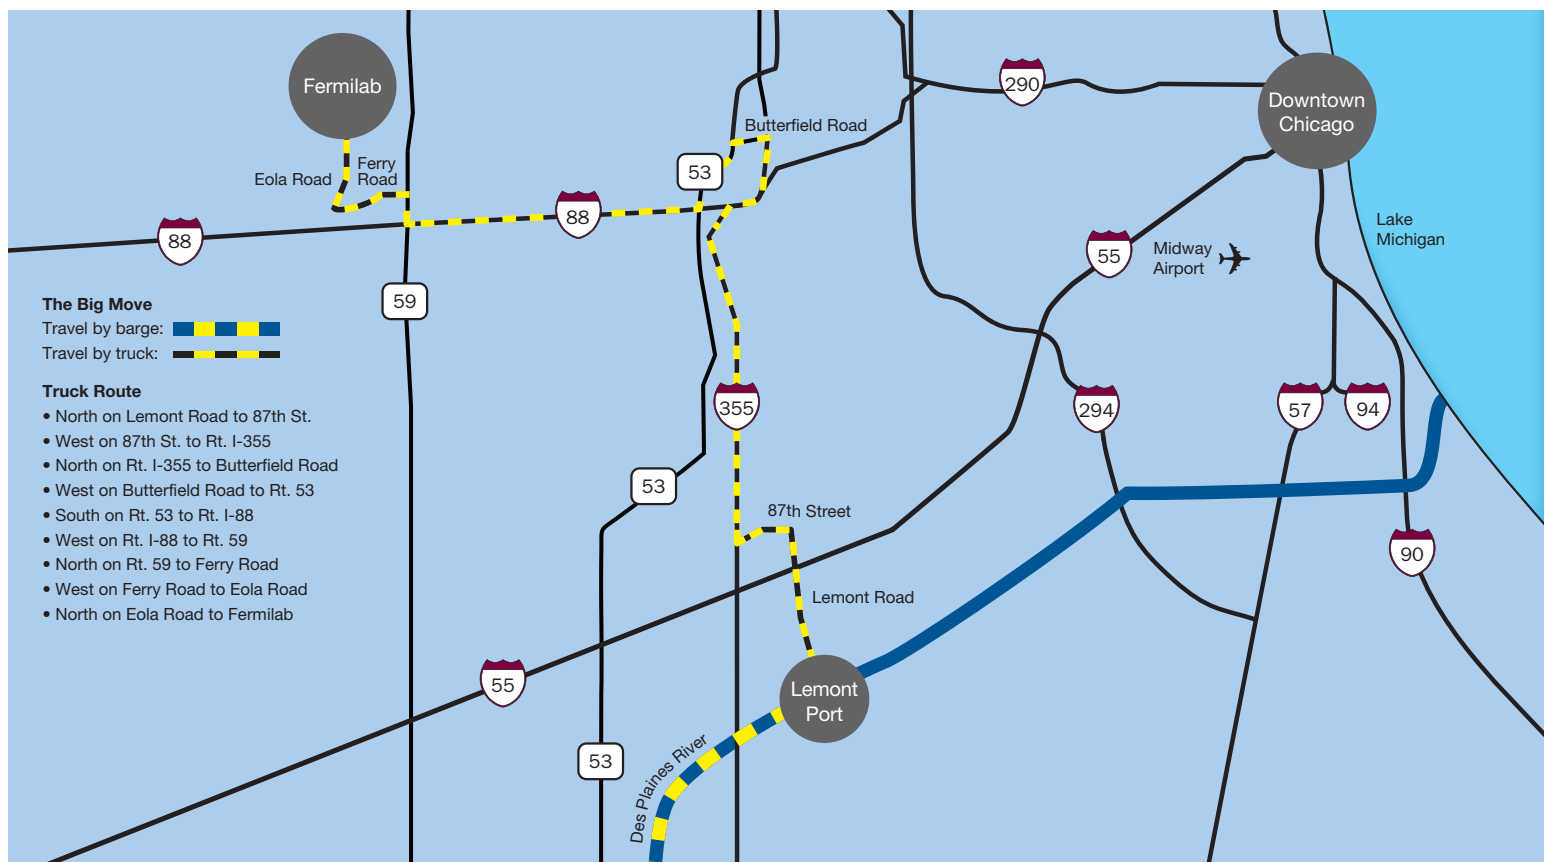

The ring, which cannot be tilted more than a few degrees, will be carefully transported from Brookhaven to a nearby port on a specially designed truck. It will then be transferred to a barge, which will bring it south around Florida and then up the Mississippi River, and finally into a port in Lemont, Illinois. From there, it will be loaded on to the back of another special truck and driven to Fermilab. The truck will move at night at about 5 miles per hour, with escort from police and other officials.

This is one of the widest loads ever to be transported across roads in Illinois, so the proposed route would take it along the widest roads available, including stretches of I-355 and I-88. Portions of the roads would be closed as the truck passes through, to minimize traffic delays. The move would take place overnight and no disruption of commuter traffic is expected.

You can follow along with the move and get more information about Muon g-2 at the project's website: gm2.fnal.gov. If you have questions about this project, please contact the Fermilab Office of Communication at 630-840-3351.
